Stata to R :: CHEAT SHEET

stata

Introduction

This cheat sheet summarizes common Stata commands for econometric analysis and provides their equivalent expression in R.

References for importing/cleaning data, manipulating variables, and other basic commands include Hanck et al. (2019). *Econometrics with R*, and Wickham and Grolemund (2017), R for Data Science.

Example data comes from Wooldridge Introductory Econometrics: A Modern Approach. Download Stata data sets here. R data sets can be accessed by installing the `wooldridge` package from CRAN.

All R commands written in base R, unless otherwise noted.

Setup

Note: While it is common to create a `log` file in Stata to store the commands and output of Stata sessions, the equivalent does not exist in R. A more savvy version in R is to create a R-markdown file to capture code and output.

ssc install outreg2 // install `outreg2` package. Note: unlike R packages, Stata packages do not have to be loaded each time once installed.

install.packages("wooldridge") # install `wooldridge` package

data(package = "wooldridge") # list datasets in `wooldridge` package

load(wage1) # load `wage1` dataset into session

?wage1 # consult documentation on wage1 dataset

Basic plots

example data:`wage1`

hist(wage) // histogram of `wage` hist(wage), by(nonwhite) // scatter(wage educ) // scatter plot of `wage` by `educ' twoway (scatter wage educ) (lfit wage educ) // scatter plot with fitted line graph box wage, by (nonwhite) // boxplot of wage by `nonwhite`

Summarize Data

example data: `wage1`

Where Stata only allows one to work with one data set at a time, multiple data sets can be loaded into the R environment simultaneously, and hence must be specified with each function call. *Note:* R does not have an equivalent to Stata's `codebook` command.

browse // open browser for loaded data

describe // describe structure of loaded data summarize // display summary statistics for all variables in dataset

list in 1/6 // display first 6 rows

tabulate educ // tabulate `educ` variable frequencies tabulate educ female // cross-tabulate `educ` and `female` frequencies

View(wage1) # open browser for loaded `waqe1` data

str(wage1) # describe structure of `wage1` data

summary(wage1) # display summary statistics for `wage1` variables head(wage1) # display first 6 (default) rows data tail(wage1) # display last 6 rows

table(wage1\$educ) #tabulate `educ frequencies table("yrs_edu" = wage1\$educ, "female" = wage1\$female) # tabulate `educ` frequencies name table columns

Tip: The {AER} package will automatically load other useful dependent packages, including: {car}, {lmtest}, {sandwich} which are used for many of the commands listed in this cheat sheet.

Estimate Models, 1/2

OLS

example data: `wage1`

.....

reg wage educ // simple regression of `wage` by `educ` (Results printed automatically).

reg wage educ if nonwhite==1 // add condition with if statement

req wage educ exper, robust // multiple regression using HC1 robust standard errors

reg wage educ exper, cluster(numdep) // use clustered standard errors

Tip: An alternate way to compute robust standard errors in **R** for any models not covered by {estimatr} package is load the {AER} package and run:

coeftest(mod1, vcov. = vcovHC, type = "HC1")

MLE (Logit/Probit/Tobit)

logit inlf nwifeinc educ // estimate logistic regression

probit inlf nwifeinc educ // estimate logistic regression

tobit hours nwifeinc educ, ll(0) // estimate tobit regression, lower-limit of y censored at zero

Postestimation, 1/2 example data:`wage1`

Note: Postestimation commands in Stata apply to the most recently run estimation commands.

example data:`mroz`

req wage educ // estimation used for the following post-estimation

predict yhat // get predicted values from last estimation, store as `yhat`

predict e, res // get residuals from last estimation, store as `e mod1 <- lm(wage ~ educ, data =</pre> wage1) # simple regression of wage by educ, store results in mod1

summary(mod1) # print summary of `mod1` results

mod2 <- lm(wage ~ educ, data =</pre> wage1[wage1\$nonwhite==1,]) # add condition with if statement

mod3 <- estimatr::lm_robust(wage ~</pre> educ + exper, data = wage1, se_type = "stata") # multiple regression with HC1 (Stata default) robust standard errors, use {<u>estimatr</u>} package

mod4 <- estimatr::lm_robust(wage ~</pre> educ + exper, data = wage1, clusters = numdep) # use clustered standard errors.

mod_log <- glm(inlf~nwifeinc + educ</pre> + family=binomial(link="logit"),

.....

data=mroz) # estimate logistic regression

mod_pro <- glm(inlf~nwifeinc + educ</pre> + family=binomial(link="probit"),

data=mroz) # estimate logistic regression

mod_tob <- AER::tobit(hours ~</pre> nwifeinc + educ, left = 0, data = mroz) # estimate tobit regression, lower-limit of y censored at zero, use {**AER**} package

mod1 <- lm(wage ~ educ, data =</pre> wage1) # estimation used for the following post-estimation commands yhat <- predict(mod1) # get</pre> predicted values

e <- residuals(mod1) # get residual</pre> values

stata

Create/Edit Variables example data: `wage1`

.....

Note: where Stata only allows one to work with one data set at a time, multiple data sets can be loaded into the R environment simultaneously, hence the data set must be specified for each command.

gen exper2 = exper^2 // create `exper` squared variable egen wage avg = mean(wage) // create average wage variable

drop tenursq // drop `tenursq` variable

keep wage educ exper nonwhite // keep selected variables

tab numdep, gen(numdep) // create dummy variables for `numdep`

recode exper (1/20 = 1 "1 to 20)years") (21/40 = 2 "21 to 40 years") (41/max = 3 "41+ years"),gen(experlvl) // recode `exper` and gen new variable

Statistical tests / diagnostics

reg lwage educ exper // estimation used for examples below

estat hettest // Breusch-Pagan / Cook-Weisberg test for heteroskedasticity

estat ovtest // Ramsey RESET test for omitted variables

ttest wage, by(nonwhite) // independent group t-test, compare means of same variable between groups

wage1\$exper2 <- wage1\$exper^2 #</pre> create `exper` squared variable wage1\$wage_avg <- mean(wage1\$wage) #</pre> create average wage variable

wage1\$tenursq <- NULL #drop `tenursq`</pre>

wage1 <- wage1[, c("wage", "educ".</pre> "exper", "nonwhite")] # keep selected variables

wage1 <fastDummies::dummy_cols(wage1, select_columns = "numdep") # create dummy variables for `numdep`, use {**fastDummies**} package

wage1\$exper1v1 <- 3 # recode `exper`</pre> wage1\$experlvl[wage1\$exper < 41] <- 2</pre> wage1\$exper]v][wage1\$exper < 21] <- 1</pre>

example data: `wage1`

mod <-lm(lwage ~ educ exper, data =</pre> wage1) # estimate used for examples below

Imtest::bptest(mod) # Breusch-Pagan / Cook-Weisberg test for heteroskedasticity using the {<u>lmtest</u>} package

Imtest::resettest(mod) # Ramsey RESET test

t.test(wage ~ nonwhite, data = wage1) # independent group t-test

Interactions, categorical/continuous variables

example data: `wage1`

In Stata, it is common to use special operators to specify the treatment of variables as continuous (c.) or categorical (`i.`). Similarly, the `#` operator denotes different ways to return the interaction of those variables. Here we show some common uses of these operators as well as their R equivalents.

reg lwage i.numdep // treat `numdep` as a factor variable

reg lwage c.educ#c.exper // return interaction term only

reg lwage c.educ##c.exper // return full factorial specification

reg lwage c.exper##i.numdep // return full, interact continuous and categorical

lm(lwage ~ as.factor(numdep), data = wage1) # treat `numdep` as factor lm(lwage ~ educ:exper, data =

wage1) # return interaction term only

lm(lwage ~ educ*exper, data = wage1) # return full factorial specification

lm(wage ~ exper*as.factor(numdep), data = wage1) # return full, interact continuous and categorical

Estimate Models, 2/2

Panel/Longitudinal

xtset id year // set `id` as entities (panel) and `year` as time variable xtdescribe // describe pattern of xt data xtsum // summarize xt data xtreg mrdrte unem, fe // fixed effects regression

Instrumental Variables (2SLS) example data: `mroz

ivreg lwage (educ = fatheduc), first // show results of first stage regression etest first // test IV and

endogenous variable

ivreg lwage(educ = fatheduc) // show results of 2SLS directly

Post-estimation, 2/2 example data: `wage1`

Note: Postestimation commands in Stata apply to the most recently run estimation commands.

example data: `murder

reg lwage educ exper##exper // estimation used for following postestimation commands

estimates store mod1 // stores in memory the last estimation results to `mod1`

margins // get average predictive margins

margins, dydx(*) // get average marginal effects for all variables marginsplot // plot marginal effects

margins, dydx(exper) // average marginal effects of experience

margins, at(exper=(1(10)51)) // average predictive margins over exper` range at 10-year increments

estimates use mod1 // loads `mod1 back into working memory

estimates table mod1 mod2 // display table with stored estimation results

plm::is.pbalanced(murder\$id, murder\$year) # check panel balance with {**plm**} package modfe <- plm::plm(mrdrte ~ unem,</pre>

index = c("id", "year"),model = "within", data = murder) # estimate fixed effects ("within") model summary(modfe) # display results

modiv <-AER::ivreg(lwage ~ educ |</pre> fatheduc, data = mroz) # estimate 2SLS with {<u>AER</u>} package

summary(modiv, diagnostics = TRUE) # get diagnostic tests of IV and endogenous variable

mod1 <- lm(lwage ~ educ + exper +</pre> $I(exper^2)$, data = wage1) # Note: in R, mathematical expressions inside a formula call must be isolated with)I()

margins::prediction(mod1) # get average predictive margins with {margins} package

m1 <- margins::margins(mod1) # get</pre> average marginal effects for all variables

plot(m) # plot marginal effects

summary(m) # get detailed summary of marginal effects

margins::prediction(mod1, at = list(exper = seq(1,51,10))) #predictive margins over `exper` range at 10-year increments

stargazer::stargazer(mod1, mod2, type = "text") # use {<u>stargazer</u>} package, with `type=text` to display results within R. *Note*: `type=` also can be changed for LaTex and HTML output.
